Keep Claude. Give it the team's memory.

Claude writes code. Slack carries updates. SageOx helps the next agent start with the decisions behind the work—and leaves a record for the session after that.

"Can't the next agent just search Slack?"

Yes. That works when the important decision was posted, the agent knows to look for it, and the right thread wins over older or partial answers. SageOx reduces those handoff steps: it records supported coding sessions, primes each new session with concise team context, and lets agents query deeper discussions and session history when they need it.[1]

THE DIFFERENCE IN PRACTICE

Claude + Slack

- An agent or teammate posts a useful summary of the work.
- The next agent decides what to search and which answer is current.
- Reasoning stays available if it made it into the post or linked thread.

Claude + SageOx

- Supported agent sessions are captured and summarized into a repo Ledger.
- Shared rules and decisions enter the next session at startup; detailed records remain searchable.
- Humans and agents can inspect the discussion or session behind a decision.

01 / TIME

Less reconstruction

Repeated handoffs need fewer manual recaps and fewer searches for basic team context.

02 / QUALITY

More consistent decisions

Agents can consult the same conventions, prior choices, and underlying sources before changing code.

03 / SCALE

Context across tools

The same team context can serve Claude Code, Codex, and other supported agents.[2]

When is SageOx worth adding?

When decisions span sessions, people, or agents often enough that missed context causes repeated explanation or rework. For a small team with disciplined Slack notes, Claude + Slack may already be enough. The gain should be measured in faster correct handoffs—not more messages.
